

## Kubernetes Core Concepts

## The main Kubernetes objects:

- **Namespace:** A way to group and separate resources inside Kubernetes.
- **Pod:** The smallest runnable unit that holds one or more containers.
- **ReplicaSet:** Ensures a fixed number of identical Pods are always running.
- **Deployment:** Manages Pods and ReplicaSets, enabling updates and rollbacks.
- **Service:** Gives Pods a stable way to be reached over the network.

# 1) Namespace – “The Organizer”

How to organize the cluster?

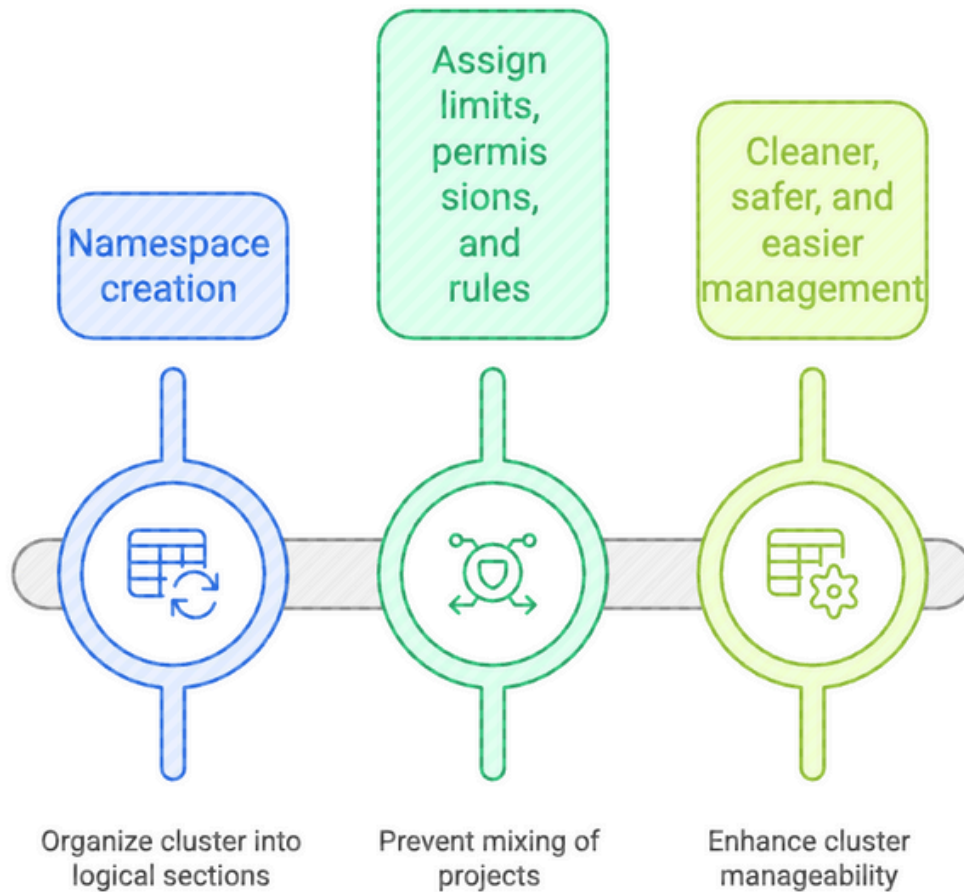

A Namespace helps you organize your cluster into logical sections.

Just like folders on a computer, it keeps different projects, teams, or environments separate.

You can assign limits, permissions, and rules per namespace to prevent everything from mixing.

## Organizing Your Cluster with Namespaces

**Why it matters:**

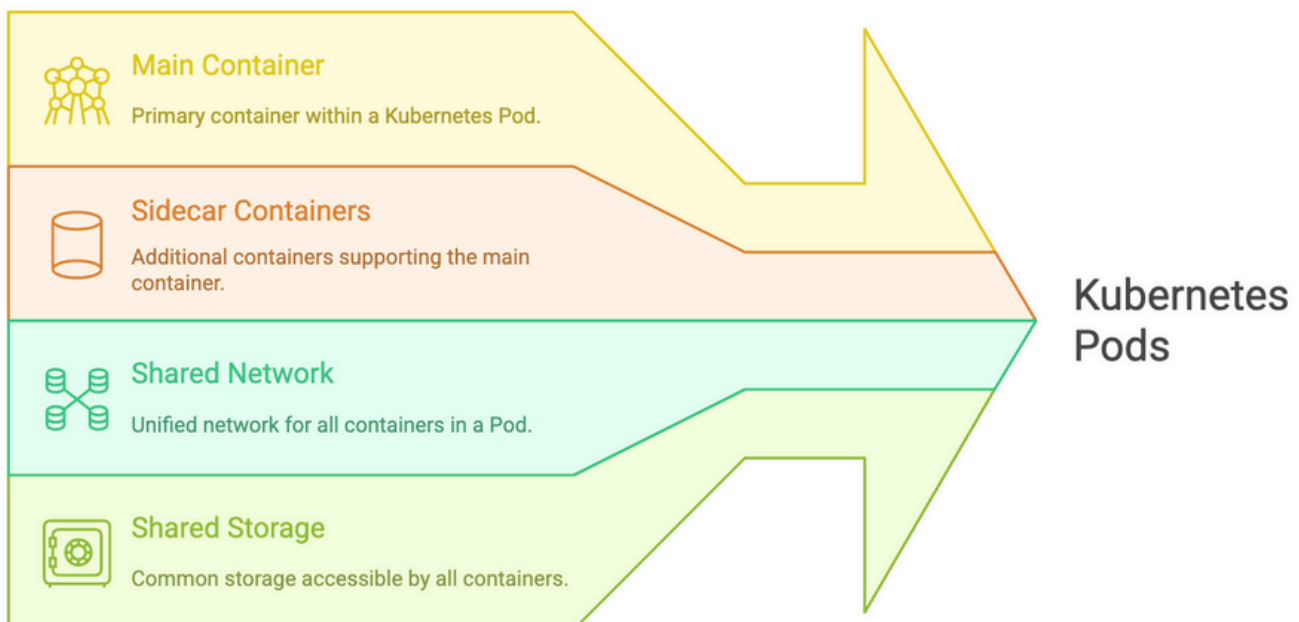

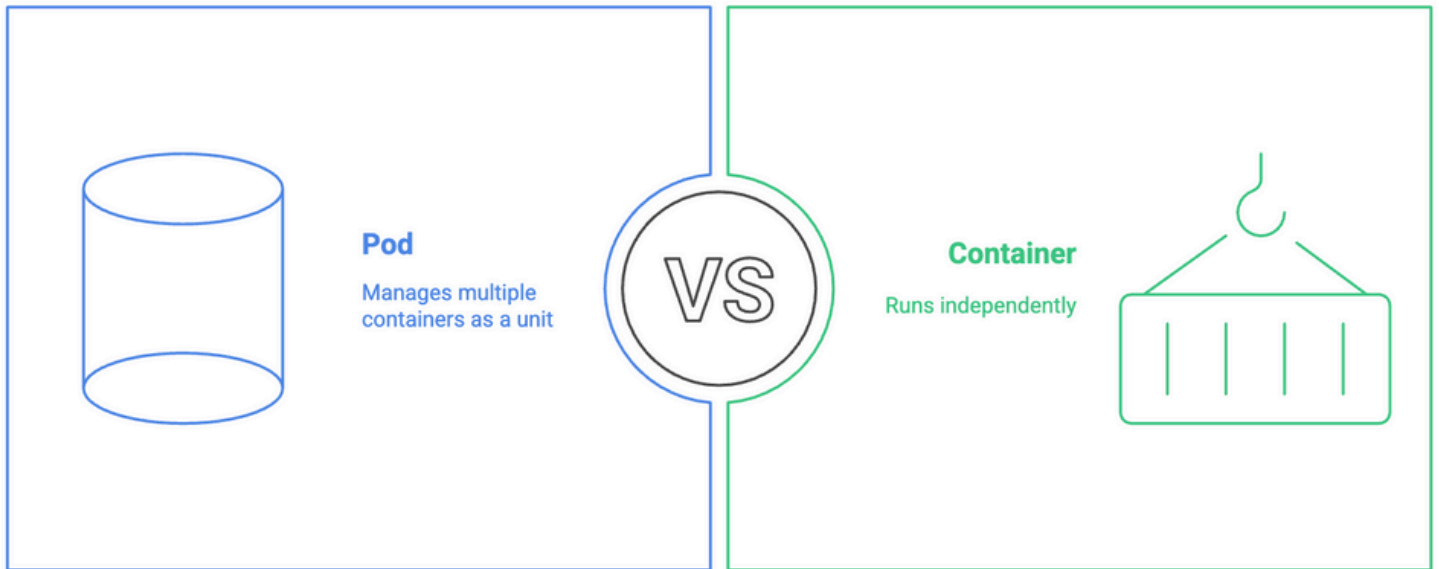

**Makes large clusters cleaner, safer, and easier to manage.**

## Kubectl Namespace Commands

Command				
	<code>`kubectl get namespaces`</code>	<code>`kubectl create namespace &lt;namespace-name&gt;`</code>	<code>`kubectl get all -n &lt;namespace-name&gt;`</code>	<code>`kubectl delete namespace &lt;namespace-name&gt;`</code>
Description	Lists available namespaces	Creates a new namespace	Lists resources in a namespace	Deletes a namespace

## 2) Pod – “The Home for Containers”

How should containers be managed in Kubernetes?

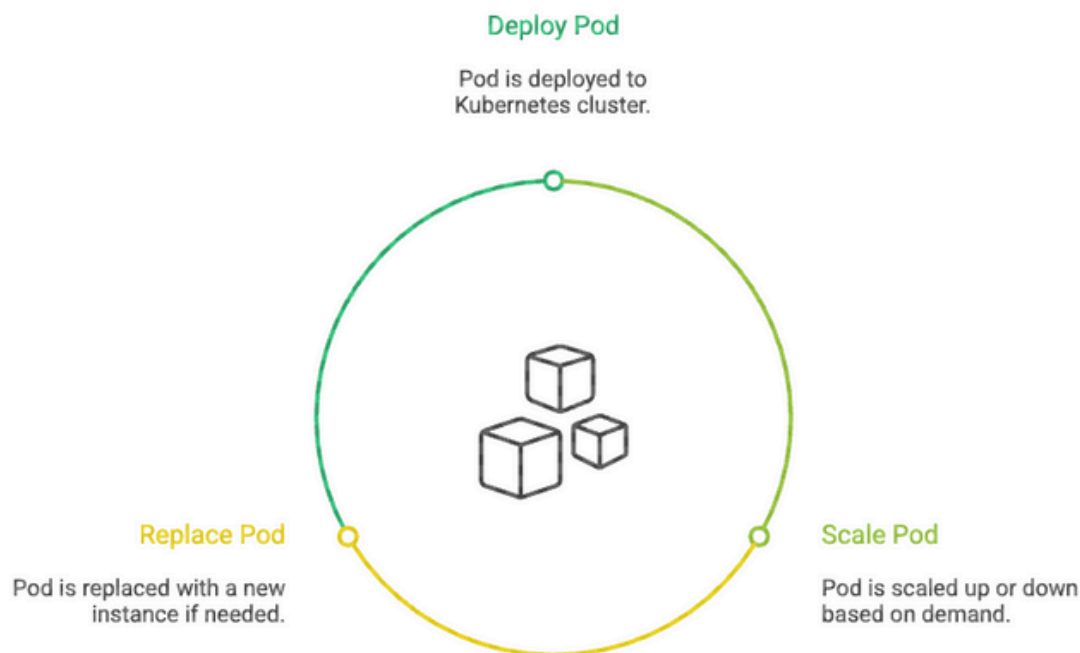

Kubernetes does not run containers directly.

It runs Pods, and a pod can contain:

- One main container
- Or multiple containers that must work closely together

Pods share the same network and storage, so the containers inside them act like a small team.

## Kubernetes Pod Lifecycle

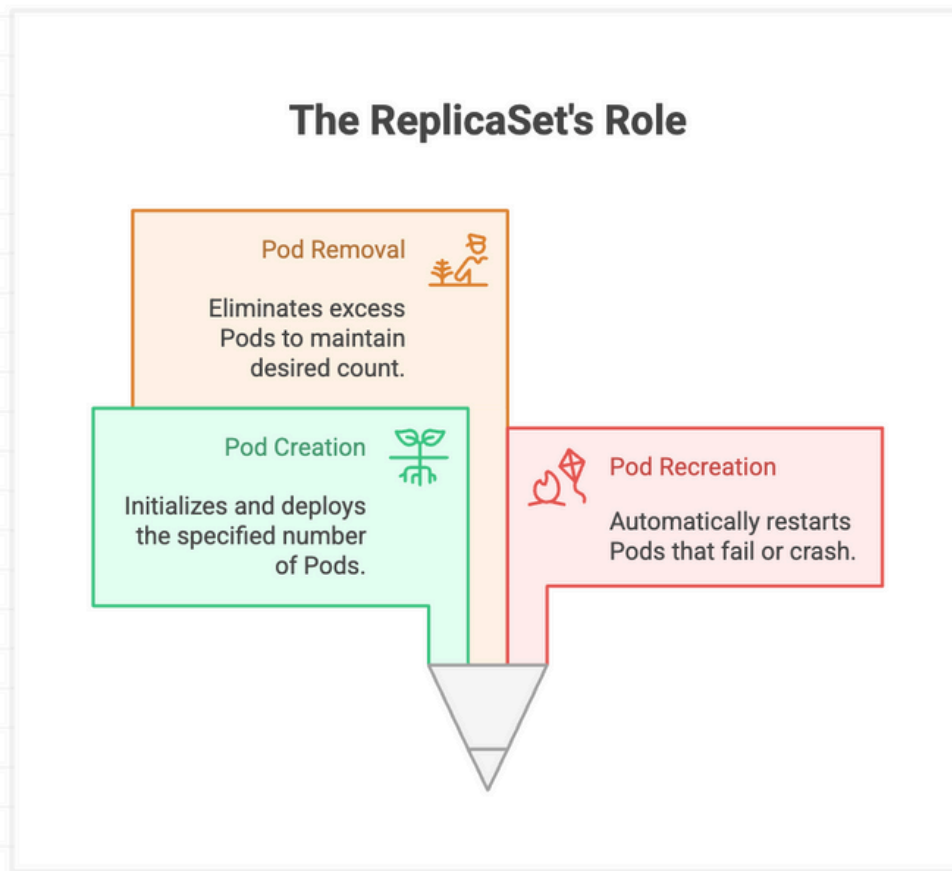

# Why it matters:

## It's the smallest unit Kubernetes can deploy, scale, or replace

### Basic PODS Commands

Command	<code>'kubectl get pods'</code>	<code>'kubectl run &lt;pod-name&gt; -- image=&lt;image-name&gt;'</code>	<code>'kubectl run &lt;pod-name&gt; -- image=&lt;image-name&gt; -n &lt;namespace-name&gt;'</code>	<code>'kubectl get pods -n &lt;namespace-name&gt;'</code>	<code>'kubectl describe pod &lt;pod-name&gt;'</code>	<code>'kubectl delete pod &lt;pod-name&gt;'</code>
Description	List pods in default namespace	Create pod in default namespace	Create pod in specified namespace	List pods in specified namespace	Describe pod	Delete pod

### 3) ReplicaSet — “The Pod Counter & Protector”

A ReplicaSet’s job is very simple and very important

**Keep the desired number of Pods running.**

If you say “I want 3 pods,” it:

- Creates them
- Recreates them when they crash
- Removes extras if more than 3 exist

# Why it matters:

## Guarantees availability and reliability.

### How to ensure pod availability and reliability?

#### Pod Creation

Creates and maintains the desired number of pods

#### Pod Protection

Recreates crashed pods and removes extras

### kubectl Commands for ReplicaSets

Command	<code>`kubectl get rs`</code>	<code>`kubectl describe rs &lt;rs-name&gt;`</code>	<code>`kubectl delete rs &lt;rs-name&gt;`</code>
Description	Lists all ReplicaSets	Describes a ReplicaSet	Deletes a ReplicaSet

## 4) Deployment – “The Manager with Upgrade Powers”

### Deployment functionalities

**A** Deployment sits above the ReplicaSet and acts as the real controller of your application.

It handles:

- Rolling updates
- Rollbacks
- Scaling
- Managing multiple app versions safely

When you change a Deployment:

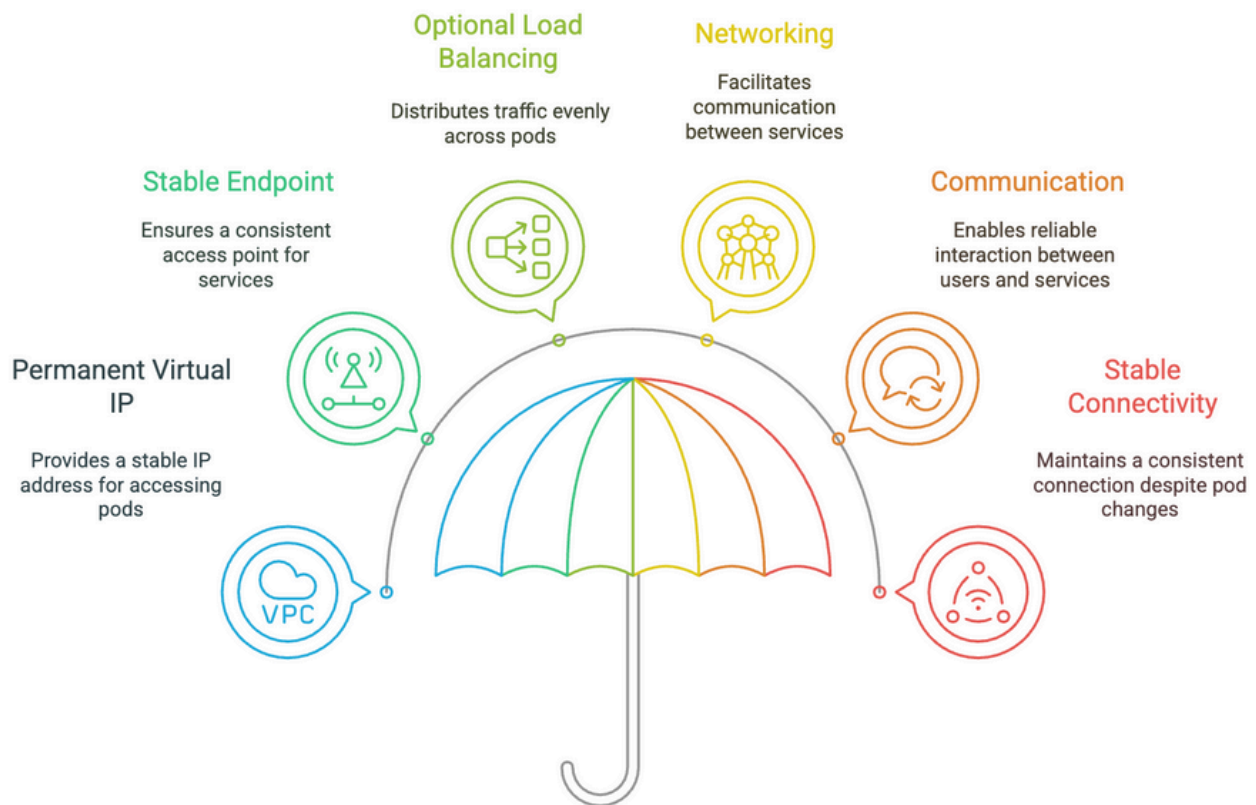

- It creates a new ReplicaSet
- Gradually replaces old pods with new ones
- Ensures zero downtime (if configured correctly)

**Why it matters:**

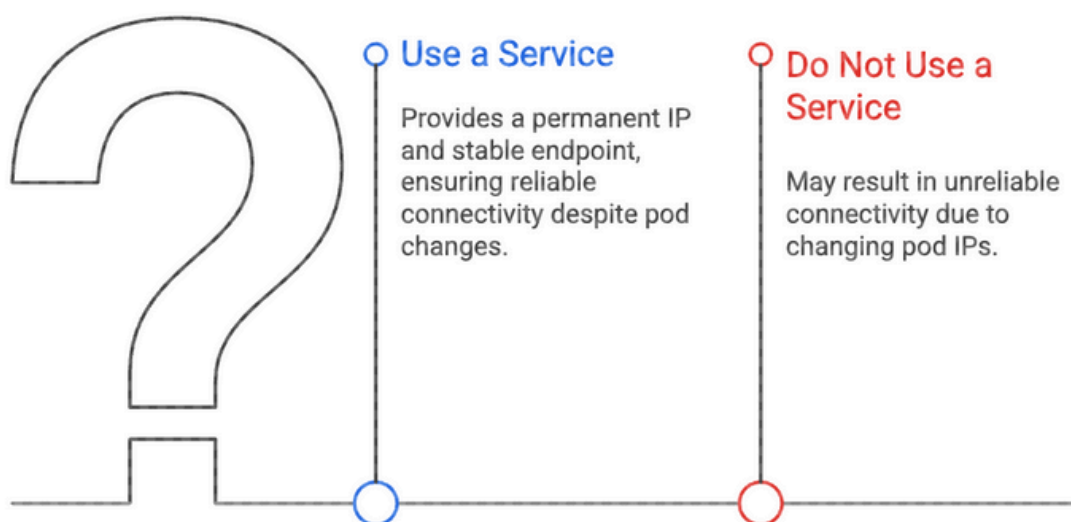

**It's the safest and most flexible way to run and update applications in Kubernetes.**

# 5) Service – “The Permanent Address”

## Understanding Kubernetes Services

## Should a Service be used for pod connectivity?

Pods come and go.

Their IPs constantly change.

A Service solves this by giving:

- A permanent virtual IP
- A stable endpoint
- Optional load balancing

It lets other services or users reach your pods reliably, even if pods keep changing behind the scenes.

**Why it matters:**

**Enables networking, communication, and stable connectivity.**
